# 集群qsub-sge.pl脚本的BUG修正

# 一、BUG说明

## 范围:

- 1. 涉及qsub-sge.pl投递任务的所有现有流程与任务。
- 2. 部分"姓名全拼过长"的员工。

#### 现象:

qsub-sge.pl投递任务后,任务尚未完成,脚本"不正常"的判定该任务已结束,若设定了`-reqsub`参数,则会导致任务无限重投。

# 二、原因

## 定位:

部分员工"姓名全拼过长",`qstat`中user信息列的姓名显示不全,命令 `whoami` 和 `qstat` 获得的uesr ID不匹配,导致脚本判定出错。

## 详细描述:

qsub-sge.pl脚本中控制检测运行任务数的子函数run\_count如下:

```
sub run_count {
       my $all p = shift;
       my $run p = shift;
       my $run_num = 0;
       %run_p = ();
       my $user = `whoami`; chomp $user;
       my $qstat_result = `qstat -u $user`;
       if ($qstat_result =~ /failed receiving gdi request/) {
               run num = -1;
               return $run_num;
       }
       my @jobs = split /\n/,$qstat_result;
       foreach my $job_line (@jobs) {
               job_line = ~s/^s+//;
               my @job_field = split /\s+/,$job_line;
               next if($job_field[3] ne $user); ###BUG所在位置,由于qstat姓名显示
不全,导致$job_field[3]和$user不匹配,所有仍在运行的任务都跳过了后续的判定,导致
$run num判定为0, 即产生"所有任务已结束"的假象。###
               if (exists $all_p->{$job_field[0]}){
                      my %died;
                       died_nodes(\%died);
                       my node_n = 1 if(\job_field[7] = /(compute-\d+-
d+)/);
                       if ( !exists $died{$node name} && ($job field[4] eq "qw"
|| $job_field[4] eq "r" || $job_field[4] eq "t") ) {
                              $run_p->{$job_field[0]} = $job_field[2]; ##job id
=> shell file name
                              $run_num++;
                       }else{
                              `qdel $job_field[0]`;
                       }
               }
       }
       return $run_num;
}
```

# 三、修复

修复办法:

命令 qstat -j jobID |grep owner 获得完整user ID,避免"姓名过长导致显示不全"的问题。

修复后:

```
sub run count {
       my $all p = shift;
       my $run p = shift;
       my $run_num = 0;
       %run_p = ();
       my $user = `whoami`; chomp $user;
       my $qstat result = `qstat -u $user`;
       if ($qstat_result =~ /failed receiving gdi request/) {
               run num = -1;
               return $run num; ##系统无反应
        }
       my @jobs = split /\n/,$qstat_result;
       foreach my $job_line (@jobs) {
               job_line = ~s/^s+//;
               my @job_field = split /\s+/,$job_line;
               my $owner=`qstat -j $job_field[0]|grep owner`;##add by
ykc,20161031;
               \sum_{w+1}^{w+1} \frac{1}{w+1};##add by ykc,20161031;
               my $user_qstat=$1;##add by ykc,20161031;
               #next if($job_field[3] ne $user);
               next if($user_qstat ne $user);##add by ykc,20161031;
               if (exists $all_p->{$job_field[0]}){
                       my %died;
                       died_nodes(\%died); ##the compute node is down, 有的时候节
点已死, 但仍然是正常状态
                       my node name = 1 if(\ field[7] = /(compute-\d+-
d+)/);
                       if ( !exists $died{$node_name} && ($job_field[4] eq "qw"
|| $job_field[4] eq "r" || $job_field[4] eq "t") ) {
                               $run_p->{$job_field[0]} = $job_field[2]; ##job id
=> shell file name
                               $run num++;
                       }else{
                               `qdel $job_field[0]`;
                       }
               }
        }
       return $run_num; ##qstat结果中的处于正常运行状态的任务,不包含那些在已死掉节点
上的僵尸任务
}
```
